(54) White blood cell differentiation composition and method.

(55) A composition and method for differentiating white blood cells, the composition comprising at least one surfactant and at least one dilute acid which together selectively strip the cytoplasm from certain classes of white blood cells and not others. More particularly, the composition causes lysis of lymphocytes, monocytes, eosinophils and neutrophils, but not basophils. Thus, basophils are differentiated from other PMN subclasses by their appearance as intact cells. The composition and method avoid the need for dye preparation and the vagaries of staining techniques, and can be used either manually or with instrumentation.

EP 0 177 137 A2

- 1 -

WHITE BLOOD CELL DIFFERENTIATION COMPOSITION AND METHOD

This invention relates to the field of hematology, particularly to differentiating subclasses of white blood cells.

Human white blood cells are classified as lymphocytes, monocytes and polymorphonuclear cells (PMNs). PMNs are subclassified as neutrophils, eosinophils or basophils based on the staining characteristics of their cytoplasmic granules.

Differentiation of white blood cells has commonly been accomplished by various staining techniques. Several phthalocyanin compounds are known for use as such. The first of these to be discovered is called Alcian Blue. Alcian Blue has been used for the differential staining of basophils. The copper phthalocyanin cationic dyes are not sufficiently specific to achieve the selective staining of basophils when used alone because they also stain other cells which possess polynucleotides, e.g. DNA and RNA. In addition, basophils stain because of the unique presence in them of heparin, a sulfated polysaccharide. One way of establishing the desired selectivity is to combine it with lanthanum chloride which masks the polynucleotide phosphate groups and thereby prevents them from binding the phthalocyanin anion.

The use of Alcian Blue requires a closely controlled, highly acidic pH and it is heat labile. At alkaline pH and _____

- 2 -

when exposed to heat, Alcian Blue forms particulates (insoluble dyes). This tendency to precipitate has been a long-standing problem in Alcian Blue-containing reagents. Automated analysis instruments contain components such as filters which collect these precipitates. This can interfere with the reliability of the determinations being made and even the operation of instruments on which this method is performed. It has nonetheless been considered the dye of choice because of its specificity and distinct color. For more background information on Alcian Blue, see Gilbert, et al, Basophil Counting With A New Staining Method Using Alcian Blue, Blood, 46:279-286 (1975).

Other phthalocyanin dyes have since been developed. For example, Bloom, et al, Histochemie, 2:48-57 (1960) shows the use of underivatized Astra Blue (free base) to stain biological tissues containing mucopolysaccharides, particularly mast cells. The Astra Blue free base is used in 0.5 N HCl which gives it a positive charge. The low pH allows selectivity because of the inherent strength of sulfuric acid derivatives, e.g., heparin, which is ionized at pH 0.3, as compared to the weakness of phosphoric acid derivatives, e.g., DNA, which is not ionized at low pH.

Inagaki, Acta Hematologica Japonica, 32(4):642-647 (1969), describes a method for staining basophil and mast cell granules using free base Astra Blue and a fixative solution of Acridine Orange in methanol containing 0.5 M NaCl. Inagaki examined saturated cetyl pyridinium chloride in absolute methanol and saturated Acridine in absolute methanol for the fixation of peripheral blood and bone marrow smears. Cetyl pyridinium chloride securely preserved the basophil granules and the mast cell granules, but the Astra Blue staining tended to be prevented. Acridine could not preserve these cell granules sufficiently in the above described procedure.

- 3 -

In summary, Alcian Blue and Astra Blue free base and its quaternary derivatives have been the only compounds of this type which have been known to differentiate basophils from other white blood cells. The instability of Alcian Blue reagent has been a longstanding problem. Thus, workers in the field have continued to search for compounds which selectively stain basophils, in contrast to other white blood cells. Further, dye uptake is dependent on each individual user's staining technique.

Since cellular maturation is a continuous process, the successive stages involved are difficult to differentiate. However, separate stages can be recognized in whole blood smears stained with Wright's or Giemsa stains. This classification is based on the presence, nature and number of granules and the cytoplasmic and nuclear characteristics of each cell. These classifications of white blood cells and techniques for their differentiation are well known. See, for example, Ansley, et al, U.S. Patent No. 3,741,875. However, classification of stained, intact cells based on cytoplasmic and nuclear information is very dependent upon subjective characterization by the user.

Kim, U.S. Patent No. 4,099,917, has disclosed a method of preparing a blood sample for discrimination between classes of unstained white blood cells by their cell size and granularity characteristics. A blood sample is treated with a detergent which lyses red blood cells but does not lyse white cells, a fixative is added and the preparation is incubated. The cell suspension so obtained is said to allow differentiation of unstained, fixed, intact white cells by optical systems having low and high angle light scatter characteristics. This requires large complex instrumentation and, thus cannot be done by visual observation.

- 4 -

Ledis, et al, U.S. Patent No. 4,286,963 discloses a composition comprised of (a) at least one long chain alkyl trimethyl quaternary ammonium salt, such as hexadecyl trimethyl ammonium bromide and (b) at least one additive selected from (i) a short chain alkanol substituted by phenyl or phenoxy, such as 2-phenoxyethanol and (ii) a polyhydroxy compound such as sorbitol for lysing red cells so that a differential determination of lymphoid and myeloid populations of white blood cells can be made.

10

Thus, most of the known techniques for this differentiation require the preparation and use of stains or provide for lysis only of red blood cells. Some require complex instrumentation. Otherwise, reported differentiation in whole cells, whether stained or unstained, is very much dependent upon subjective characterization. Nothing in the literature describes a reliable method for simultaneously determining an accurate basophil count and a lobularity index in the same sample of treated blood and in the absence of a stain.

20

Groner, et al, Blood Cells, 6:141-157 (1980) discusses differentiation of white blood cell subclasses using optical scatter, staining properties and other techniques. The concept of "left shift" is mentioned, referring to a trend in neutrophil populations toward more immature or less lobulated forms. A sharp change in index of refraction was created at the nuclear boundary by treating a whole blood sample with a strong cationic detergent and maleic acid. As a result, the red blood cells were lysed, most of the cytoplasm of the leukocytes was leached, and the nucleus shrank slightly. From the discussion in this reference, it appears that the leukocyte membranes were not ruptured or lysed (as mentioned with reference to red blood cells), leukocyte cytoplasm was not completely (only mostly) stripped leaving artifacts which distort the apparent shape of the nucleus and, finally, there is no mention of differentiation of the effect of this treatment between one leukocyte subclass and any other.

- 5 -

In contrast to the techniques offered by the prior art and in accordance with the present invention, it is now possible to provide a precise characterization of nuclear morphology (lobularity) and to differentiate among sub-
5 classes of PMNs based on the cytoplasmic stripping of certain sub-classes and not others. The composition selectively removes cytoplasm from certain classes of white blood cells and not others. More particularly, the composition causes cytoplasmic removal from lymphocytes, monocytes, eosinophils
10 and neutrophils, but not basophils. Thus, basophils are differentiated from other PMN sub-classes by their retention of granules and cytoplasmic membrane. In addition, since nucleated red blood cells are detected, the invention allows for their quantitation as well.
15

The potential error arising from cytoplasmic artifacts adhering to the nuclei of all blood cells other than basophils, thus altering the apparent shape of the nuclei, is avoided by complete stripping of cytoplasmic material from
20 their nuclei by the composition of the invention. As such, differentiation of blast cell, nucleated red cells and of the various maturation stages of neutrophils, based on their nuclear morphology, can be made with certainty. An important advantage is that the composition and method totally avoid
25 the need for dye preparation and the resulting vagaries of staining techniques. The composition described can be used manually or with instrumentation.

The composition of the invention for differentiation of
30 white blood cells in a sample comprises at least one water-soluble surfactant and at least one dilute acid effective to strip cell membranes and cytoplasm from selected subclasses of white blood cells and not others, and has a pH of from about 1.8 to about 2.3. The surfactant can, for example, be

- 6 -

a C₆-C₁₆ aliphatic alcohol ether of a poly alkylene glycol, a quaternary ammonium compound having a C₆-C₁₆ alkyl group or an alkyl benzene sulfonate. The acid is preferably a sulfonic or carboxylic acid or hydrochloric acid.

5

The invention further provides a method for differentiating subclasses of white blood cells. A blood sample is treated to strip the cell membranes and cytoplasm from selected subclasses of white blood cells and the subclasses are then differentiated based on their nuclear morphology. More particularly, the membrane and cytoplasm are completely stripped from all subclasses of leukocytes other than basophils.

In order that the invention may be more fully understood, reference is made to the accompanying drawings, wherein:

- 7 -

Figs. 1A-1E are two-dimensional distribution plots of the scattering patterns of individual white blood cells in cell suspensions analyzed, using a composition of the invention, in a flow cytometer. Each white blood cell is represented by 5 a black dot and each plot shows the observed patterns at a successive stage of the reactions carried out in the experiments described in Example II.

Fig. 2 is a two-dimensional distribution plot showing the 10 distribution of basophil counts (not individual cells) in samples tested as described in Example II.

Fig. 3 is a two-dimensional distribution plot showing the distribution of mononuclear cell counts (not individual 15 cells) in samples tested as described in Example II.

Fig. 4 is a two-dimensional distribution plot showing the distribution of polymorphonuclear cell counts (not individual cells) in samples tested as described in Example II.

20

Figs. 5A-5B are two-dimensional distribution plots of an abnormal whole blood sample known to contain immature granulocytes which were obtained using the composition of the invention and a conventional methodology, respectively.

25

Figs. 6A-6F are two-dimensional distribution plots illustrating the ability of the disclosed chemistry to indicate left shift as compared to a conventional methodology.

30

Figs. 7A-7C are two-dimensional distribution plots of individual blood samples analyzed, using a composition of the invention, in a flow cytometer. They illustrate the results obtained in the experiments of Example III on samples from a

- 8 -

donor with acute myeloblastic leukemia, a normal donor and a donor with chronic lymphocytic leukemia, respectively.

5 Figs. 7D-7F are two-dimensional distribution plots of the experiments performed in Example III using a conventional methodology.

10 Figs. 8A-8B are two-dimensional distribution plots of the scattering patterns of individual white blood cells in cell suspensions passed through a flow cytometer using a composition in accordance with the invention and a conventional peroxidase reagent, respectively, as described in Example IV.

- 9 -

Specific terms in the following description, which refer to only a particular embodiment, are exemplary of all of the embodiments unless otherwise indicated.

5 As previously indicated, the composition of the invention selectively strips the cytoplasm of certain classes of white blood cells and not others. Lymphocytes, monocytes, eosinophils and neutrophils are cytoplasmically stripped. That is, their membrane and cytoplasmic material are stripped from
10 their nuclei which are left unaffected and free of associated cytoplasmic material. Thus, the morphology of their nuclei is sharply defined. In contrast to the cytoplasmic removal so affected, basophils retain their granules and cytoplasmic membrane.

15 The novel composition of this invention finds application in manual or flow cytometric detection of various blood cell types. The composition disclosed herein is comprised of a water-soluble surfactant and a dilute acid and has a pH range
20 of from about 1.8 to about 2.3. It can also, optionally, include an antioxidant. For performance of the assay, the surfactant and dilute acid component(s) must be present. Omission of either component yields a non-functional composition. The chain terminating antioxidant prevents autoxidative degradation of the surfactant which leads to deterioration of the cytoplasmic stripping function. In the absence
25 of the antioxidant, the composition shelf-life is two months when stored at 25°C. However, when the antioxidant is present, the shelf-life is at least one year at 25°C. The
30 antioxidant does not interfere with proper functioning of the composition.

The water soluble surfactant can be any surfactant which provides the required action on blood cells: complete lysis

- 10 -

of red cells and platelets, loss of cytoplasm and cell cytoplasmic membrane of neutrophils, eosinophils, lymphocytes and monocytes and retention of granules and cell membrane for basophils. Examples include: (i) C₆-C₁₆ aliphatic alcohol ethers of a polyalkylene glycol, preferably polyoxyethylene or polyoxypropylene, such as Brij-35 (ICI America, Wilmington, DE); (ii) C₆-C₁₆ aliphatic N,N-dialkyl N-oxides, such as dodecyl-N, N-dimethyl amine N-oxide; (iii) C₆-C₁₆ aliphatic ammonium salts, such as tetradecylammonium bromide; (iv) 10 quaternary ammonium compounds having a C₆-C₁₆ alkyl group, such as cetyl trimethyl ammonium bromide or cetyl pyridinium chloride; (v) alkylbenzene sulfonates, such as sodium dodecyl benzenesulfonate; and (vi) mixtures thereof.

15 The invention also requires the presence of at least one dilute acid. Examples include: (i) organic sulfonic acids, such as methane sulfonic acid or ethane sulfonic acid; (ii) carboxylic acids, such as maleic, phthalic, oxalic, malonic, glycine, dichloroacetic and lactic acids; and (iii) mixtures 20 thereof. It can also be advantageous to use at least one dilute inorganic acid. Examples include hydrochloric, hydrobromic, sulfuric and phosphoric acid. For present purposes, "dilute" refers to concentrations of about 30 mM or less. Particularly useful are combinations of mineral acids and 25 carboxylic acids, such as phthalic acid-HCl.

The reagent composition, as used in analyzing samples with which it is contacted, must have a pH range of from about 1.8 to about 2.3. Although this is a narrow pH range, 30 it is an important aspect of the invention. This pH can be established by the presence of the dilute, acid, alone, or can be effected by including additional acids.

The composition can also, optionally, include a chain-terminating antioxidant which will retard the degradation of

the surfactant as a result of autoxidation, thus enhancing shelf life. The antioxidant destroys peroxy radicals which, if not inhibited, would participate in chain reactions. Examples include di-tert-butyl-4-methylphenol (BHT), p-
5 methoxy phenol (MEHQ) or di-tert-butyl-4-methoxyphenol (BHA).

The composition can also, optionally, include an anti-microbial preservative which will retard or prevent the
10 growth of contaminating organisms such as mold.

In the preferred embodiments of this invention, the ingredients are used in the proportionate ranges:

15	a) surfactant	10-20g/l
	b) dilute acid	0.020-0.024 M/l
	c) chain terminating antioxidant	0.1-0.2 g/l
	d) antimicrobial preservative	0.2-0.6 g/l

20 It is desirable to be able to control the reaction rate so that the method can be optimized for either manual or automated modes. In this regard, compositions comprised of Brij-35, maleic acid and BHT are of particular interest. Maleic acid may be utilized over a concentration range of
25 0.025%-1% (0.0022 - 0.086 M). The effect of variation of the maleic acid concentration leads to a net increase in the rate of about tenfold.

30 The lower range of concentration of maleic acid is particularly useful for manual microscopic work. The reaction rate is slow enough such that the procedure can be accomplished within two minutes. In contrast, at the higher end of the range, the reaction is essentially instantaneous and is appropriate for automated instrumental techniques.

In practicing the method of the invention, it has been observed that when whole blood is mixed with a solution of surfactant and dilute acids, there is a sequence of membrane and cytoplasmic destruction which begins with red blood cell 5 lysis leaving no structure of the red blood cell behind, platelet lysis which also leaves no structure behind, and white blood cells cytoplasmic stripping leaving bare nuclei of all white blood cells but for basophils which remain substantially intact as the only whole cells observable in the 10 treated blood sample. The white blood cell nuclei and the basophils which retain their cytoplasmic membrane and granularity can be differentiated by visual observation or through an instrumental detection system.

15 It is preferred to introduce the cell sample into a fluid stream flowing in a conduit or analysis channel in a flow cytometer. This preferably comprises establishing a flowing stream of a sheath fluid in the conduit or analysis channel and thereafter introducing the sample into the flowing sheath 20 stream. Such sheath streams are usually of fluids having a refractive index substantially identical to that of the cell sample suspending medium. One such flow cytometer which uses a sheath stream carrier fluid is used in the Technicon Hemalog D and H-6000 systems, which handle all routine hematology 25 tests. Detailed information on the Hemalog D and H-6000 systems is available from Technicon Instruments Corporation, Tarrytown, NY.

The following working examples describe experiments 30 which were performed in developing the present invention. In summary, the results in these examples demonstrate that the composition and method of the invention make it possible to (a) obtain accurate basophil counts; (b) provide an indication of the mean lobe count or amount and severity of left 35 shift present in any given sample; (c) obtain accurate differentiation of blast cells from other mononuclear cells;

0177137

- 13 -

(d) quantitate and identify nucleated red blood cells; and
(e) obtain a total white blood cell count. Standard commercially available reagent grade chemicals were used whenever possible.

EXAMPLE IMANUAL DIFFERENTIAL WHITE BLOOD CELL COUNT

A differential white blood cell (WBC) count is one of the most important distinguishing parameters in the differential diagnosis of various disease states, particularly relating to infectious and immunological disorders. In the experiment 5 reported by this example the composition of the invention was prepared and used in differentiating basophils from all other blood cells and mononuclear from polymorphonuclear white blood cells.

10 The composition of the invention was prepared in 97 milliliters (ml) of distilled water by adding 0.20 grams (g) of maleic acid and 3 ml Brij-35 (made to 30% weight/volume (w/v) in distilled water).

15 An 8.0 microliter (ul) sample of fresh whole human blood was mixed with 500 ul of the composition prepared as described above. After one minute an aliquot of the reacted whole blood sample was pipetted onto a clean microscope slide for observation under 40x power through a Nikon microscope.

20 Upon microscopic examination of this aliquot it was observed that the red blood cells and platelets were destroyed and white blood cells, other than basophils, of the sample had been completely cytoplasmically stripped. The 25 cytoplasmic membrane and granules of basophilic PMNs had been unaffected and remained intact.

Compositions were also prepared which were like those described above but for the absence of maleic acid. This 30 composition was used for testing blood samples as described above and no lysis of blood components was observed. Also,

0177137

- 15 -

compositions were prepared in which maleic acid was present,
but the surfactant, Brij 35, was omitted. Cellular clumping
was observed to occur which obscured recognition of basophils
and of white blood cell lobularity. As such, neither of
these compositions was effective to provide the differentia-
tion made possible by the composition of the invention.

EXAMPLE IIAUTOMATED DIFFERENTIAL WHITE BLOOD CELL COUNT

The experiments reported in this example show the use of the composition of the invention in making an accurate basophil count. Basophils, mononuclear cells (immature granulocytes, lymphocytes and monocytes) and PMNs (neutrophils and 5 eosinophils) were determined. They were compared (correlated) with the same determinations made by existing techniques as used on the H-6000 instrument system (Technicon, supra). A determination of the presence of immature granulocytes is illustrated. Also, the composition of the invention was used to determine left shift, e.g., decrease in mean 10 neutrophil lobe count.

A reagent composition was prepared, in accordance with the invention, to contain 3.6 g phthalic acid, 10 g Brij-35; 15 0.1 g BHT; 1.0 ml of 1N HCL; and was made up to 1 liter with distilled H₂O (pH 2.0).

Blood samples from each of a large panel of patients were examined using the same test procedure for each. An 8 ul 20 volume of each blood sample was placed in a separate test tube along with 500 ul of the above reagent composition. After 50 seconds of mixing, the reaction mixture was peristaltically pumped through a sheath stream flow cell at a flow rate of 0.1 ml/min.

25 The optical system used to obtain two-dimensional distributions of cell-by-cell light scattering signatures was that of a modified RBC/PLT channel of a Technicon H-6000 flow cytometry system (Technicon, supra). High angle scatter was 30 measured along the abscissa and low angle scatter was measured along the ordinate in the output provided by the

system. Threshold lines of demarcation were set by computer using cluster analysis to distinguish between various cell types and the system was programmed to ignore all the signals due to cellular debris and the like. A complete description 5 of the optics system used is available from Technicon, supra. The output signals from this optics system were amplified and converted into a two-dimensional distribution plot. Each dot represented the measured coordinates of a single cell.

10 Each of the samples taken from the panel of patients was analyzed using the above composition and procedure in accordance with the invention. Figures 1A-1E represent the stages of the reaction from the above analysis procedure on one of such samples, from a normal donor, at different time intervals from initiation of the reaction. Fig. 1A (15 seconds) shows RBCs and PLTs which have been destroyed (R) and swollen WBCs (W). Fig. 1B (20-25 seconds) shows lymphocytes (L) which have started to lose their cytoplasm and move along the Y-axis toward the origin. In Fig. 1C (30-35 seconds) 15 some granulocytes (G) have begun to lose their cytoplasm and all lymphocytes (L) have undergone complete cytoplasmic stripping. In Fig. 1D (40-45 seconds) most granulocytes (G) and all lymphocytes (L) have been completely cytoplasmically stripped and, thus, have moved to their final X-Y positions. 20 Fig. 1E (80 seconds) shows that all white blood cells, except for basophils (B), have been stripped of their cytoplasm, leaving only bare nuclei, and are in their final X-Y positions. Distinct clusters of PMNs (P), mononuclear cells (MN), baso- 25 phils (B), and cellular debris (R) are shown.

The samples taken from the panel of patients were also tested on a conventional, commercially available Technicon H-6000 system in accordance with the manufacturer's directions. 30 The correlation of the results for each of the basophil,

mononuclear cell (MN) and PMN clusters is represented by Figs. 2-4, respectively.

Fig. 2 shows a Rumpke Oval placed on the data from 98 samples, normal and abnormal, comparing the method of the invention against the Technicon H-6000 basophil chemistry for percent basophils. This Figure shows excellent agreement along with the fact that more than 95% of the points fall within the oval. A correlation coefficient of 0.81 was observed.

Fig. 3 shows excellent accuracy and correlation for mononuclear cells (MN) using the disclosed chemistry and mononuclear cells, including lymphocytes (L), monocytes (M) and large unstained cells (LUC), using the Technicon H-6000 peroxidase chemistry. The number of samples was reduced to eliminate abnormal (leukemic) samples to indicate how well the method of invention agrees on normal samples. A correlation coefficient of 0.96 was observed.

20

Fig. 4 shows the excellent accuracy and correlation for PMNs on the same samples reported, using the disclosed chemistry (P) and the H-6000 system, which reports PMNs as neutrophils (N) and eosinophils (E). A correlation coefficient of 0.97 was observed.

Figs. 5A and 5B are two-dimensional distribution plots of an abnormal sample known to contain immature granulocytes using the disclosed chemistry and the conventional H-6000 system peroxidase chemistry, respectively. A more densely populated cluster of mononuclear cells is observed in Fig. 5A, than would be expected from the peroxidase chemistry lymphocytes, monocytes plus large unstained cells. The percentage of cell types reported using each of the above methods, and as observed manually, is set forth in Table I.

35

TABLE I

	<u>Mononuclear</u>	<u>PMN</u>	<u>Immature G</u>
Discl. Chem.	39.6%	57.9%	NA
H-6000	31.6%	67.7%	NA
5 Manual	33.5%	59.0%	7.5%

The substantial difference in the number of mononuclear cells observed between the disclosed method and H-6000 method corresponds with the number of immature granulocytes observed 10 by the manual method. Therefore, samples containing significant numbers of immature granulocytes can be distinguished from normal samples.

Another benefit of the disclosed chemistry, because of 15 the preservation of only the nuclei of the neutrophil, is its ability to indicate the presence of a left shift (i.e., a decrease in the mean neutrophil nuclear lobe count caused by the presence of a greater number of band cells). This is demonstrated by the fact that as the mean lobe count 20 decreases, the mode of the PMN cluster (P) decreases. Figs. 6A-6C show the H-6000 method for three samples with increasing band counts and decreasing mean lobe counts. It can be seen that these three samples have no distinguishing characteristics to suggest which sample has the left shift. 25 Figs. 6D-6F show the same samples using the disclosed chemistry. It can be seen that as the mean lobe count decreases, there is a corresponding decrease in the mode of the PMN cluster (P). This movement to the left of the PMN cluster mode allows the disclosed chemistry to predict the presence 30 of a left shift. Table II shows the manual band count and manual mean neutrophil lobe count versus the mode of the PMN cluster (P) for these samples, ranging from 0-20 band cells and mean lobe counts from 3.38 down to 2.31.

0177137

- 20 -

TABLE II

<u>Manual Band Count</u>	<u>Manual Mean Lobe Count</u>	<u>PMN Mode</u>
0% (Fig. 6D)	3.38	30.5
5% (Fig. 6E)	3.06	27.0
5 20% (Fig. 6F)	2.31	24.5

EXAMPLE III

The experiments reported in this example show the use of the same composition and method of analysis of the invention as described in Example II for differentiating blast cells from other mononuclear cells. Significant percentages of 5 large unstained cells observed using the H-6000 system peroxidase chemistry have been attributed to the presence of abnormal mononuclear cells. Such methods have not been able to identify these as either blast cells or atypical lymphocytes.

10

Whole blood samples were obtained from a donor with acute myeloblastic leukemia (sample A), a normal donor (sample B) and a donor with chronic lymphocytic leukemia (sample C). The pattern of cell clusters for each when analyzed using the 15 composition of the invention is illustrated by Figs. 7A-7C, respectively.

Another aliquot of each of these same three samples was stained for peroxidase activity and analyzed using the conventional peroxidase reagents and channel on an H-6000 system. The results reported are illustrated in Figs. 7D-7F, 20 respectively.

Figs. 7A and 7C both show a substantial population of 25 large unstained cells (LUCs). As such, they are indicative of the presence of abnormal mononuclear cells and can be differentiated from Fig. 7B, representing the normal population distribution. However, Figs. 7A and 7C appear substantially identical to one another, thus providing no way to 30 determine whether these increased LUC populations are due to an increase in blast cells, indicative of acute myeloblastic leukemia, or atypical lymphocytes, indicative of chronic lymphocytic leukemia.

- 22 -

Figs. 7D and 7F show a significant difference in the position of the mononuclear (MN) clusters as they appeared along the X axis. The MN cluster in Fig. 7D, having moved to the left, toward the origin, contains the blast cells. In 5 contrast, the MN cluster in Fig. 7F remained in the same position as that of the MN cluster in Fig. 7E, which is that of the normal donor. By placing a fixed, vertical blast threshold (BT) one can obtain an accurate last percent.

10 The percentages of blast cells observed, using a manual method and the disclosed chemistry, and the percentage of large unstained cells using the H-6000 chemistry are shown in Table III.

15

TABLE III

	<u>% Blasts</u>		<u>% LUCs</u>
	<u>Manual</u>	<u>Disclosed</u>	<u>H-6000</u>
20	22.0%	23.18% (Fig. 7D)	31.4% (Fig. 7A)
	0%	0.64% (Fig. 7E)	2.3% (Fig. 7B)
	0%	0.17% (Fig. 7F)	41.2% (Fig. 7C)

Thus, it has been demonstrated that, using the composition of the invention, it is now possible to distinguish 25 between blast cells and atypical lymphocytes. This provides a mode of differentiating between significantly different classes of leukemias.

EXAMPLE IV

The experiment reported in this example used the same composition and method of analysis as described in Example II. For quantitatively determining nucleated red blood cells (NRBC) the presence of immature, nucleated red blood cells in 5 circulating blood is a significant abnormal finding which, until now, could not be instrumentally determined.

A sample of whole blood containing nucleated red blood cells was mixed with the composition of the invention and 10 analyzed. The results are shown in Fig. 8A. A dense cluster of cells appears in the PMN region (P). Another aliquot of the same sample was stained for peroxidase activity and analyzed using the conventional peroxidase reagents and channel on an H-6000 system. The results obtained were as 15 shown in Fig. 8B. Only scattered cells appeared in the region where neutrophils (N) and eosinophils (E) usually appear.

Thus, the conventional peroxidase methodology detects 20 almost no PMNs, while the method of the invention detects a significant PMN population which proved to be the nucleated red cells, as confirmed by visual examination. This proved to be the difference in the absolute cells per lambda between the PMN count using the conventional H-6000 system methodology and the PMN count using the method of the invention. 25

CLAIMS

1. A composition for differentiation of white blood cells in a sample, the composition comprising at least one water soluble surfactant and at least one dilute acid effective to strip cell membranes and cytoplasm from selected subclasses of white blood cells and not others, the composition having a pH of from about 1.8 to about 2.3.
2. A composition according to claim 1, wherein the surfactant comprises a C₆-C₁₆ aliphatic alcohol ether of a polyalkylene glycol, preferably a polyoxyethylene or polyoxypropylene glycol; or a C₆-C₁₆ aliphatic N,N-dialkyl N-oxide, preferably dodecyl-N,N-dimethyl amine N-oxide.
3. A composition according to claim 1, wherein the surfactant comprises a C₆-C₁₆ aliphatic ammonium salt, preferably tetradecylammonium bromide.
4. A composition according to claim 1 wherein the surfactant comprises a quaternary ammonium compound having a C₆-C₁₆ alkyl group, preferably cetyl trimethyl ammonium bromide or cetyl pyridinium chloride.
5. A composition according to claim 1, wherein the surfactant comprises an alkyl benzene sulfonate, preferably sodium dodecyl benzene sulfonate.
6. A composition according to any of claims 1 to 5, wherein the dilute acid comprises a sulfonic acid, preferably methane sulfonic acid or ethane sulfonic acid, or

a carboxylic acid, preferably maleic, phthalic, oxalic, malonic, dichloroacetic and lactic acid or glycine, or hydrochloric acid, or a mixture of a dicarboxylic acid and a mineral acid, such as a mixture of phthalic acid and 5 hydrochloric acid.

7. A composition according to any of claims 1 to 6, which further comprises a chain-terminating antioxidant, preferably di-tert-butyl-4-methyl-phenol or di-tert-butyl-10 4-methoxyphenol.

8. A method for differentiating subclasses of white blood cells, which method comprises the steps of treating a blood sample to strip the cell membranes and 15 cytoplasm from selected subclasses of said white blood cells and, thereafter, differentiating said subclasses of white blood cells based on their nuclear morphology.

9. A method according to claim 8, wherein treating a 20 sample to strip cell membranes and cytoplasm from selected subclasses of white blood cells comprises stripping cell membranes and cytoplasm from white blood cells other than basophils.

25 10. A method according to claim 9, wherein treating said sample comprises treating it with a composition as claimed in any of claims 1 to 7.

(54) White blood cell differentiation composition and method.

(57) A composition and method for differentiating white blood cells, the composition comprising at least one surfactant and at least one dilute acid which together selectively strip the cytoplasm from certain classes of white blood cells and not others. More particularly, the composition causes lysis of lymphocytes, monocytes, eosinophils and neutrophils, but not basophils. Thus, basophils are differentiated from other PMN subclasses by their appearance as intact cells. The composition and method avoid the need for dye preparation and the vagaries of staining techniques, and can be used either manually or with instrumentation.
